# HKUST Future-Ready Scholars Introduction to Game Programming using Python

Part 2

4 May 2024

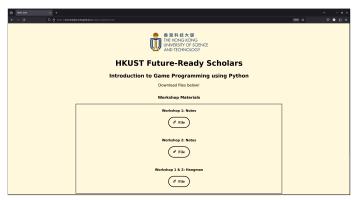

# Google Colab

Login to your Gmail account.

Then head to https://colab.research.google.com/

#### **Files**

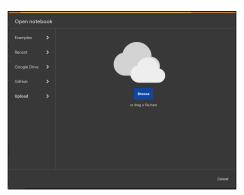

# All materials today are at: https://bit.ly/ustidpo

Download all files that belong to Workshop 2.

# Jupyter Notebook

Now upload your Jupyter Notebook file with **Files** → **Open Notebook**.

Upload the file Hangman.ipynb.

# Using Jupyter Notebook

You can type your code in these blocks. We call these blocks code cells.

You can run a code cell with the button on the left.

Let's look at what we learnt last time.

# Examples of valid integers

```
a = 5
```

b = 1000000

c = -1984

#### Examples of valid strings

```
a = "5"
```

b = "haha"

c = 'some words'

## Arithmetic Operators

#### Some basic and commonly-used operators:

+: add -: minus,

\*: multiply /: divide

## The print() statement

print(\*objects)

\*objects - the things you want to print (put on the screen)

## The input() statement

input(prompt)

where prompt is quite literally what it means. It prints the prompt, then returns the value inputted as a string.

#### random.randint()

random.randint(a, b)

a - the lower bound of your range

b - the upper bound of your range

This generates an integer n where  $a \le n \le b$ .

#### if, elif and else

if, elif and else clauses are used to decide whether some code should be executed. Whenever one is fulfilled, all others are ignored.

```
if condition1: # if condition1 is true
    # Do something, ignore all elif and else below
elif condition2: # if condition2 is true
    # Do something, ignore all elif and else below
elif condition3: # if condition3 is true
    # Do something, ignore all elif and else below
else: # if all the conditions above are false
    # Do something
```

## The and logic operator

The and operator makes it so that both conditions have to be fulfilled in order for the code it is under to execute.

## The or logic operator

The or operator makes it so that only 1 of the conditions have to be fulfilled in order for the code it is under to execute.

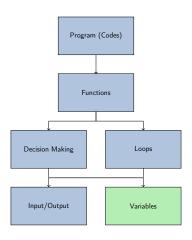

### The not logic operator

The not operator reverses the condition is it attached to.

## Multiple logic operators

One can chain multiple logic operators together, but to be safe add brackets () to make sure the condition works as intended.

## Contents

Imagine you have a bunch of variables you want to store. For example, if you have a bunch of people's names.

```
name0 = "Chris Wong"
name1 = "Desmond Tsoi"
name2 = "Phoebe Mok"
name3 = "Nancy Ip"
```

That is annoying to store and access.

What if instead, we store it in the same thing, as a... list?

Lists are declared by surrounding the items with [], and separating each item with a comma.

We can get the name from a list by getting the corresponding item.

How? With list[index].

The first item in the list is the  $0^{th}$  item, second is  $1^{st}$  item, etc...

We call this zero-indexing.

Note: Some programming languages use one-indexing instead.

If you approach another programming language, be careful.

#### Another example:

## Printing the whole list

To print the whole list, simply put it in the print() function.

To get the length of a list, we can use the len() function.

```
numbers = [0, 1, 1, 2, 3, 5]
print(len(numbers)) # 6
```

To edit an element of a list, assign the new value to the correct index.

```
numbers = [0, 1, 1, 2, 3, 5]
print(numbers) # [0, 1, 1, 2, 3, 5]
numbers[1] = 100 # Edit the second element (index 1)
print(numbers)
# Output: [0, 100, 1, 2, 3, 5]
```

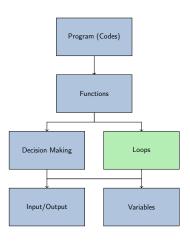

To add an element to the end to a list, we use the append(value) list function.

```
numbers = [0, 1, 1, 2, 3, 5]
print(numbers, "length:", len(numbers))
# Output: [0, 1, 1, 2, 3, 5] length: 6
numbers.append(100) # Add 100 to the end of the list
print(numbers, "length:", len(numbers))
# Output: [0, 1, 1, 2, 3, 5, 100] length: 7
```

We can check if an element is in a list with the in operator.

```
numbers = [0, 1, 1, 2, 3, 5]
if 0 in numbers:
    print("0 is in numbers.") # This line is run
else:
    print("0 is not in numbers.")
if 8 in numbers:
    print("8 is in numbers.")
else:
    print("8 is not in numbers.") # This line is run
```

## Contents

## Loops

What do you do if you want to do something repeatedly in code?

```
print("Count:", 10)
print("Count:", 9)
print("Count:", 8)
print("Count:", 7)
print("Count:", 6)
print("Count:", 5)
print("Count:", 4)
print("Count:", 3)
print("Count:", 2)
print("Count:", 1)
print("Done.")
```

Let's turn this into a loop.

#### Example:

```
i = 10 # Initialising i as 10
while i > 0:
    print("Count:", i)
    i = i - 1
print("Done.")
Let's run through it together.
```

```
Example:
```

```
i = 10
while i > 0: # i is 10, which is larger than 0
    print("Count:", i)
    i = i - 1
print("Done.")
```

```
Example:
i = 10
while i > 0:
    print("Count:", i) # Count: 10
    i = i - 1
print("Done.")
```

```
Example:
i = 10
while i > 0:
    print("Count:", i)
    i = i - 1 # i goes from 10 to 9, then we go back up
print("Done.")
```

```
Example:
i = 10
while i > 0: # i is 9, which is larger than 0
    print("Count:", i)
```

i = i - 1
print("Done.")

```
Example:
i = 10
while i > 0:
    print("Count:", i) # Count: 9
    i = i - 1
print("Done.")
```

```
Example:
i = 10
while i > 0:
    print("Count:", i)
    i = i - 1 # i goes from 9 to 8, then we go back up
print("Done.")
```

print("Done.")

```
Example:
i = 10
while i > 0: # i is 8, which is larger than 0
    print("Count:", i)
    i = i - 1
```

```
Example:
    i = 10
while i > 0:
        print("Count:", i) # Count: 8
        i = i - 1
print("Done.")
```

```
Example:
i = 10
while i > 0:
    print("Count:", i)
    i = i - 1 # i goes from 8 to 7, then we go back up
print("Done.")
```

```
Example:
i = 10
while i > 0: # i is 7, which is larger than 0
    print("Count:", i)
    i = i - 1
print("Done.")
This goes on and on...
```

print("Done.")

```
Example:
i = 10
while i > 0: # i is 1, which is larger than 0
    print("Count:", i)
    i = i - 1
```

```
Example:
    i = 10
while i > 0:
        print("Count:", i) # Count: 1
        i = i - 1
print("Done.")
```

```
Example:
i = 10
while i > 0:
    print("Count:", i)
    i = i - 1 # i goes from 1 to 0, then we go back up
print("Done.")
```

```
Example:
```

```
i = 10
while i > 0: # i is 0, which is NOT larger than 0, so we exit
    print("Count:", i)
    i = i - 1
print("Done.")
```

# Loops - while

```
Example:
i = 10
while i > 0:
    print("Count:", i)
    i = i - 1
print("Done.") # "Done." is printed
```

## Loops - while

```
Example:

i = 10

while i > 0:

ULLUL print("Count:", i)

ULLUL i = i - 1
```

### Indentation

print("Done.")

Just like if-clauses, the indentation must be consistent for statements in the loop. This also applies to for loops, which we will get into very soon.

### Example:

```
for i in range(10):
    print("Count:", i)
print("Done.")
```

### Python range

Python range is a thing of mystery. When you do range(n), where n is an integer, Python generates a range of integers from 0 to n - 1.

```
Not getting the loop?
for i in range(10):
    print("Count:", i)
print("Done.")
is equivalent to
i = 0
while i < 10:
    print("Count:", i)
    i = i + 1
print("Done.")
Both loops go from 0 to 9, and give identical output.
```

```
Another example:
```

```
for i in range(3):
    print(i * i) # Print the square, end with a space
# Output: 0
# 1
# 4
```

```
Let's combine lists with a for loop.
words = ["haha", "hehe", "hoho"]
for i in range(len(words)):
    print(words[i]) # Print num[i]
# Output: haha
# hehe
# hoho
This is one way we go through a list.
```

Instead of using the index, there is another way to go through a list:

```
words = ["haha", "hehe", "hoho"]
for i in words:
    print(i) # Print the element
# Output: haha
# hehe
# hoho
```

The output is identical to the previous example.

#### Lists

Lists are represented with [ ] to hold multiple variables, where the  $i^{\rm th}$  item is at index i-1.

#### Lists with functions

If a list is called 1, one can:

- print the list with print(1).
- get the length of 1 with len(1).
- get/edit the element at index i with 1[i].

#### List functions

If a list is called 1, one can:

- append a value v to 1 with 1.append(v).
- use the in operator to check if a value v is in a list.

```
e.g.: if v in 1:
```

### while loops

while condition:

# Do code

Code in the while block are run while the condition is fulfilled.

Do make sure that the while loop can be exited.

### for loops and range

```
n = 5 # Example
for i in range(n):
     # Do code with each number from 0 to n - 1
range(n) returns a range of integers that starts from 0 and ends at n - 1.
```

### for loops and lists

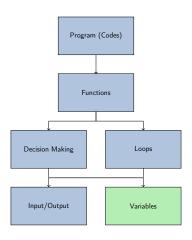

```
1 = [...] # A list with items
for i in 1:
    # Do code with each item in the list
for loops can be directly applied onto lists.
```

The End Thank you!

### Additional content

Here are some additional content that we didn't have time to mention in the workshop.

### Contents

To insert an element to a particular position in a list, we use the insert() list function.

The insert(i, value) inserts the value at index i, and push everything after to the right.

```
numbers = [0, 1, 1, 2, 3, 5]
print(numbers, "length:", len(numbers))
# Output: [0, 1, 1, 2, 3, 5] length: 6
numbers.insert(2, 100) # Add 100 to index 2 of the list
print(numbers, "length:", len(numbers))
# Output: [0, 1, 100, 1, 2, 3, 5] length: 7
numbers.insert(7, 200) # Same as numbers.append(200)
print(numbers, "length:", len(numbers))
# Output: [0, 1, 100, 1, 2, 3, 5, 200] length: 8
```

To remove an element from a list, we use the remove() list function. The remove(value) function removes the **first** occurrence of value.

```
numbers = [0, 1, 1, 2, 3, 5]
print(numbers, "length:", len(numbers))
# Output: [0, 1, 1, 2, 3, 5] length: 6
numbers.remove(1) # Remove the first occurence of number 1
print(numbers, "length:", len(numbers))
# Output: [0, 1, 2, 3, 5] length: 5
```

```
The reverse() list function reverses a list's contents.

numbers = [0, 1, 1, 2, 3, 5]

print(numbers, "length:", len(numbers))

# Output: [0, 1, 1, 2, 3, 5] length: 6

numbers.reverse() # Reverse the list

print(numbers, "length:", len(numbers))

# Output: [5, 3, 2, 1, 1, 0] length: 6

print(numbers[0])

# Output: 5
```

The count(item) list function counts the number of occurence of item in a list.

```
numbers = [0, 1, 1, 2, 3, 5]
print(numbers.count(1))
# Output: 2
print(numbers.count(100))
# Output: 0
```

The index(item) list function finds the index of the first occurrence of item in a list.

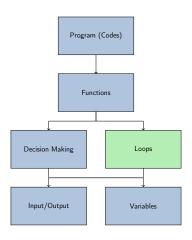

```
numbers = [0, 1, 1, 2, 3, 5]
print(numbers.index(1))
# Output: 1
print(numbers.index(5))
# Output: 5
print(numbers.index(100))
# Output: No output error 100 is referred.
```

# Output: No output, error, 100 is not in the list

```
Combining in and list.index():
numbers = [0, 1, 1, 2, 3, 5]
if 5 in numbers:
    print("The index of 5 in the list is", numbers.index(5))
# Output: The index of 5 in the list is 5
```

```
The sort() list function sorts a list's contents.
numbers = [6, 5, 1, 2, 3]
print(numbers, "length:", len(numbers))
# Output: [6, 5, 1, 2, 3] length: 5
print(numbers[0])
# Output: 6
numbers.sort() # Sort the list
print(numbers, "length:", len(numbers))
# Output: [1, 2, 3, 5, 6] length: 5
print(numbers[0])
# Output: 1
```

### Contents

### Loops - while

We can also apply boolean values to while loops.

```
equal_to_5 = False
count = 0
while not equal_to_5:
    if count == 5:
        equal_to_5 = True
    count = count + 1
print("Done.") # "Done." is printed
```

The range in Python does not always have to start at 0.

### Custom range

Given range(a, b), a for loop will iterate from a to b - 1.

### List functions

If a list is called 1, one can:

- insert a value v to 1 at index i with 1.insert(i, v).
- remove the first occurrence of a value v with 1.remove(v).
- reverse the list with 1.reverse().
- count the occurrence of value v with 1.count(v).
- get the index of the first occurrence of a value v with l.index(v).
- sort the list with 1.sort().

### Boolean conditions of while

You can apply boolean conditions to while loops.

```
status = True # Or False, or a condition with variables
while status: # Can also add "not"
     # Do something
```

### Custom range

```
Given range(a, b), a for loop will iterate from a to b - 1.
sum = 0
for i in range(100, 102):
    sum = sum + i
print(sum) # Output: 201
```
